

Example: gmail reply detection

Gmail has no native way to check if an email has been replied to

It can be implemented through threads

Need to expose this to the domain

1. Discovered how thread works through contract tests
2. Use these tests to write a simulator like gmail
3. Very productive and confident in implementing the domain logic

Example : api change

Both simulators and contract test shave been written to consume orange mails

The application was tested with simulators

Need to change end point used to read mails in the adapter (QOS issue)

1. Write the adapter with the new end point
2. Check the behavior still works as the old one and the simulator
3. Integrate the new end point safely without change neither domain code nor domain tests
